

Figure 1 displays the hallucination F_1 (%) for various models and dimensions, comparing the best anchor budget per cell (true-score $T=600$) against the true-score $T=600$. The figure is organized into a 3x4 grid of heatmaps, showing the hallucination F_1 (%) for different models (rows) and dimensions (columns). The models are: knn, quadratic, mlp (left column); altered_knn, polar2, analytic (middle column); and kernel, polar3, polar8 (right column). The dimensions are 2, 4, 8, 16, and 32. The y-axis for each heatmap represents the number of modes K (2, 4, 8, 16). The color scale ranges from 0.0 (light blue) to 1.0 (dark blue).

The heatmaps illustrate that hallucination F_1 (%) generally increases with dimension d and number of modes K . The 'analytic' model shows the highest hallucination F_1 (%) values, reaching up to 60% for $d=32$ and $K=2$. The 'knn' model shows the lowest hallucination F_1 (%) values, often dropping to 0% for higher dimensions and modes.
